

Applied Category Theory for Scientists: compositional knowledge representation

Kristopher Brown,
Evan Patterson,
Andrew Baas, Tyler
Hanks, James Fairbanks

Category theory is a field of math that studies *structure*. When we model real-world domains using categories, basic constructions of CT very often correspond to useful operations with elegant implementations.

Knowledge syntax/medium	Reasoning engine
Mathematical equations	Computer algebra
Vectors/embeddings	Deep learning
Formal logic	Auto. theorem proving
Scientific papers	Human intuition
Scripts/software ("the model is the code")	Running the code

Example of inference: constrained Rxn networks

We can represent chemical reaction networks via an alternative graphical syntax called *Petri nets*. This allows for declaring and enforcing certain high-level constraints using very basic tools, which would not be straightforward with traditional syntax.

Example Type system

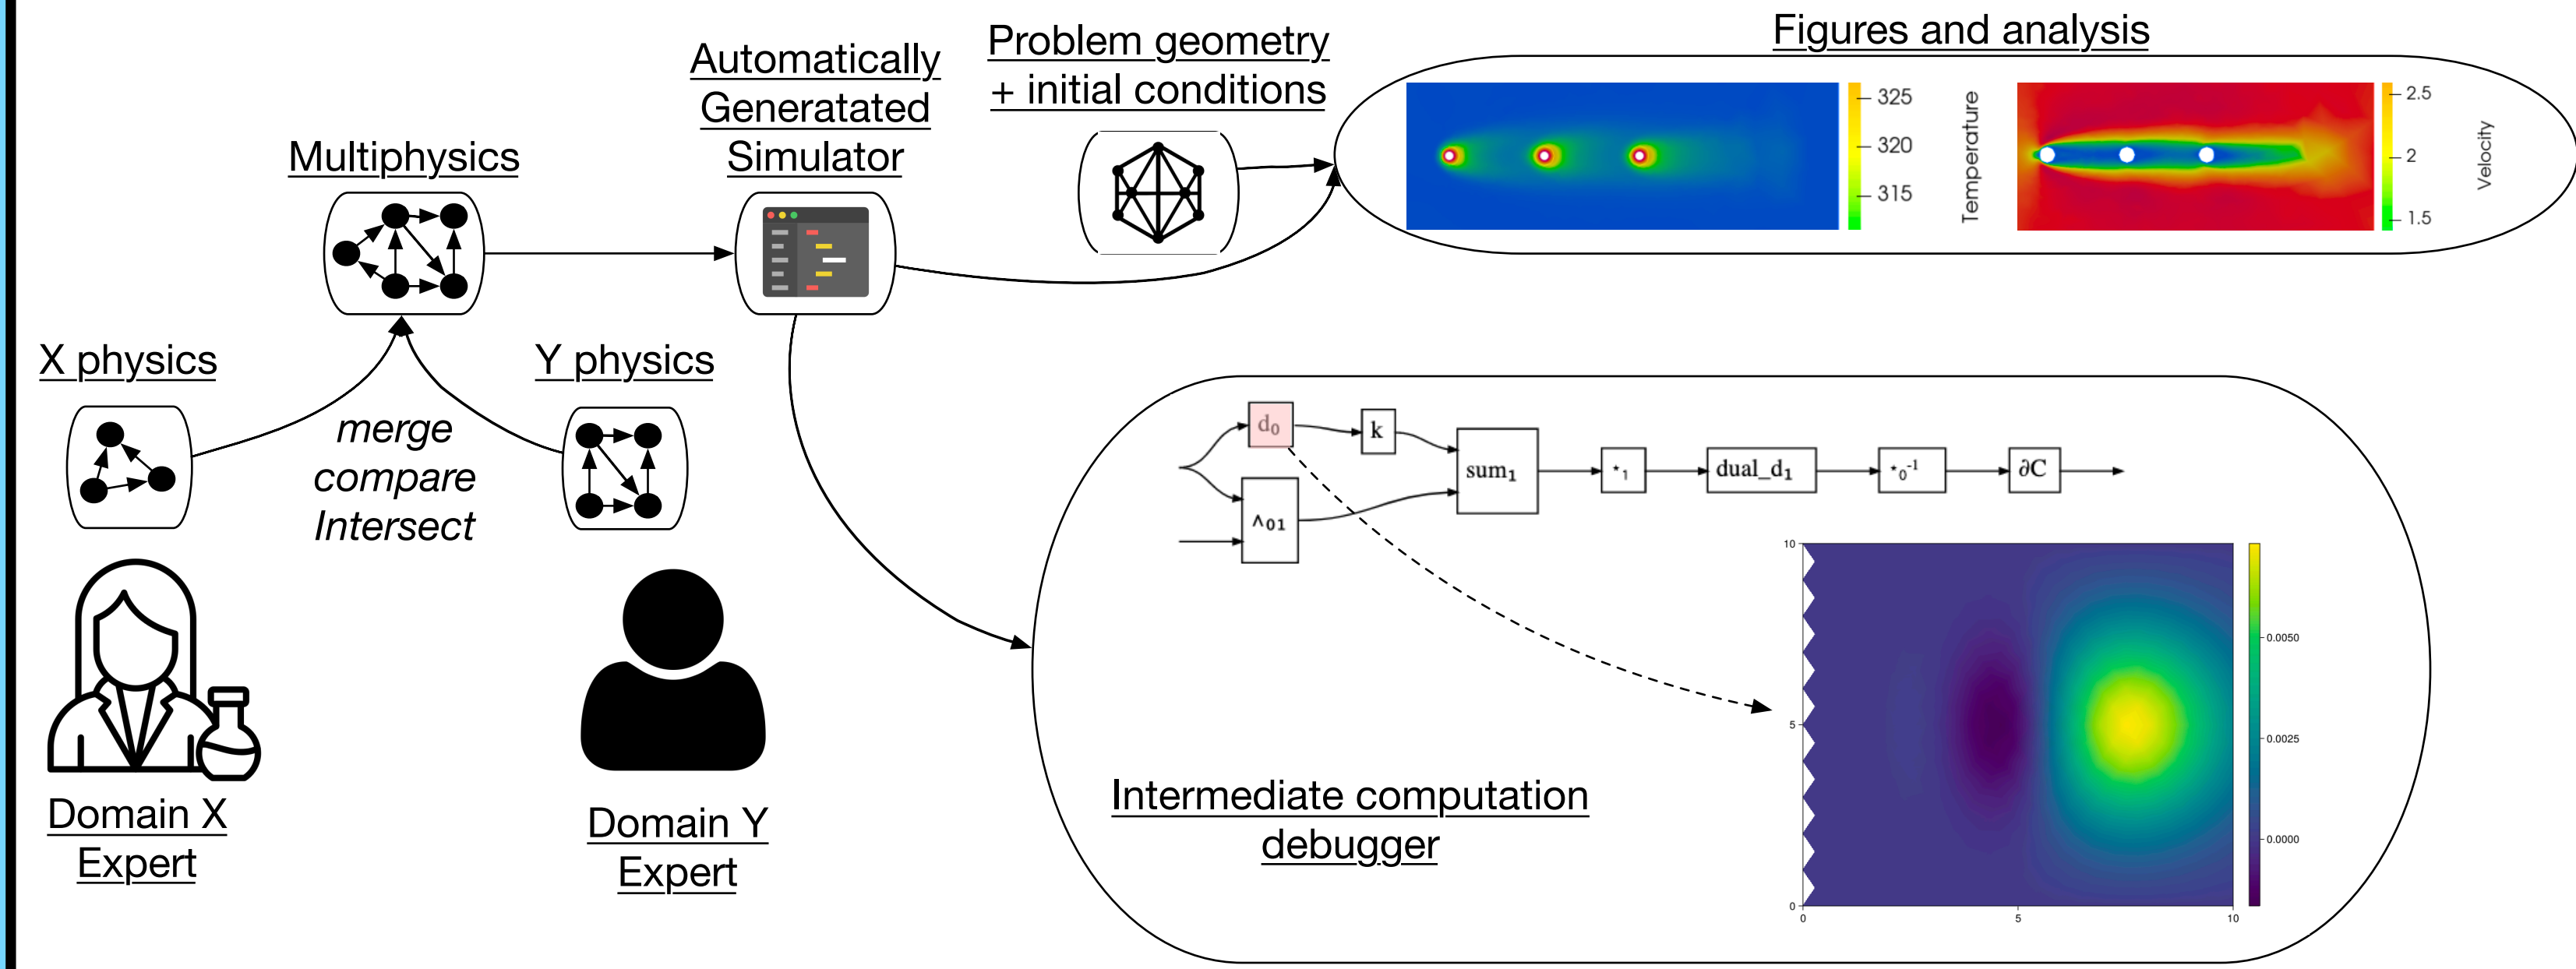

"Two types of reactions, bimolecular or unimolecular. Each reaction requires a 'reactive' species"

A very general algorithm (*homomorphism search*) can be implemented just once and applied to this kind of graph to check/enforce these constraints. It also has many other applications.

✗ Inference not automatable, doesn't scale well, or error-prone.

✓ CT facilitates separating a simple graphical syntax (easily reasoned about) + giving it semantics in a richer mathematical framework.

Multiphysics solvers specified via diagrams, generate programs which solve PDEs on meshes

Fick's law of diffusion

Mass conservation

Advection

$$T : \mathbb{R}_T \xrightarrow{k \nabla} \phi : \mathbb{R}_T^2$$

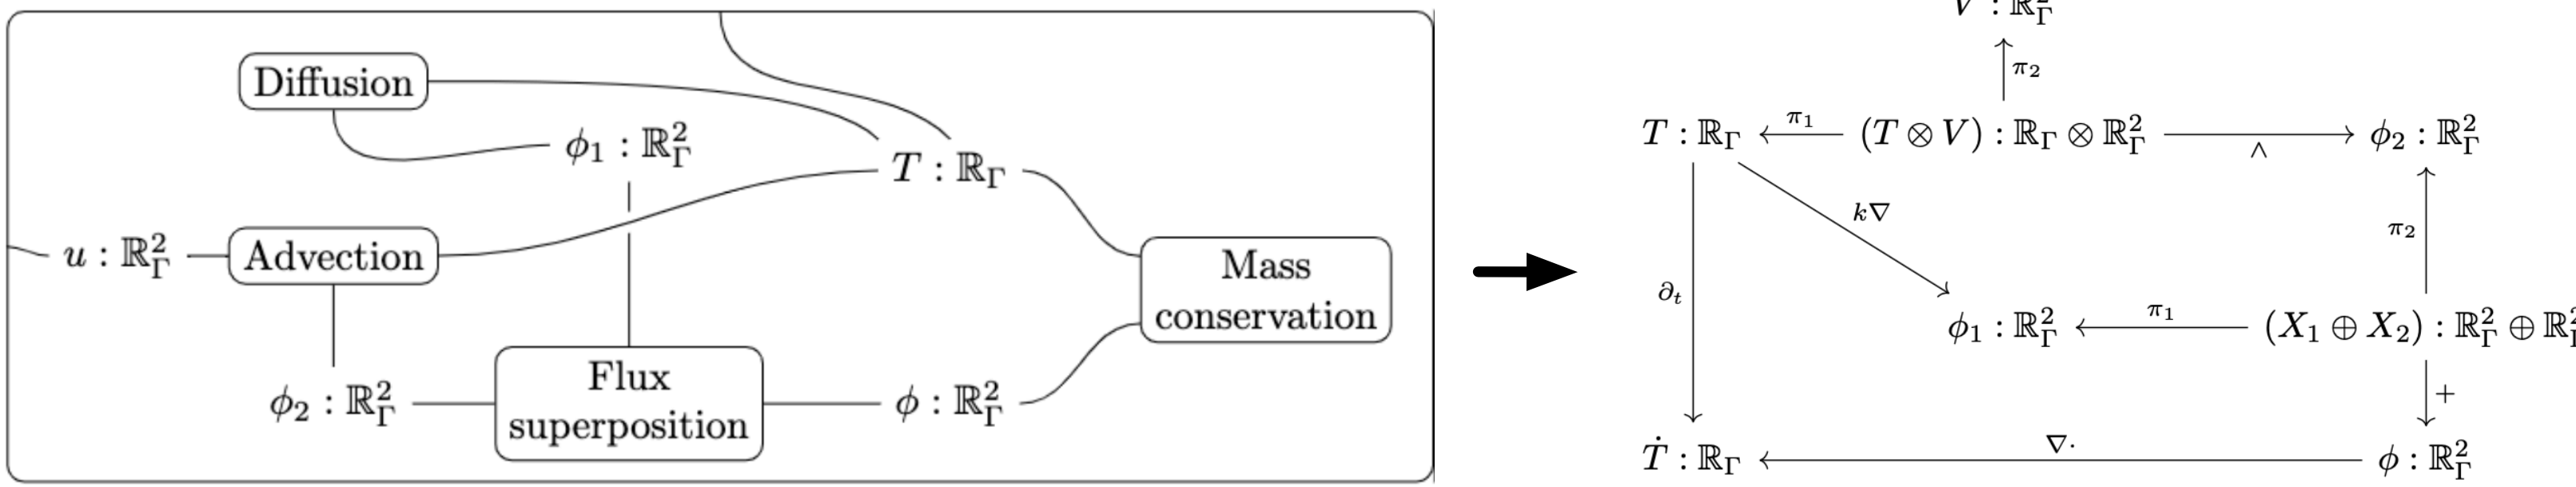

$$X : \mathbb{R}_T \xrightarrow{\partial_t} \phi : \mathbb{R}_T^2$$

$$V : \mathbb{R}_T^2 \xrightarrow{\pi_1} \phi : \mathbb{R}_T^2$$

$$T \otimes V : \mathbb{R}_T \otimes \mathbb{R}_T^2 \xrightarrow{\wedge} \phi : \mathbb{R}_T^2$$

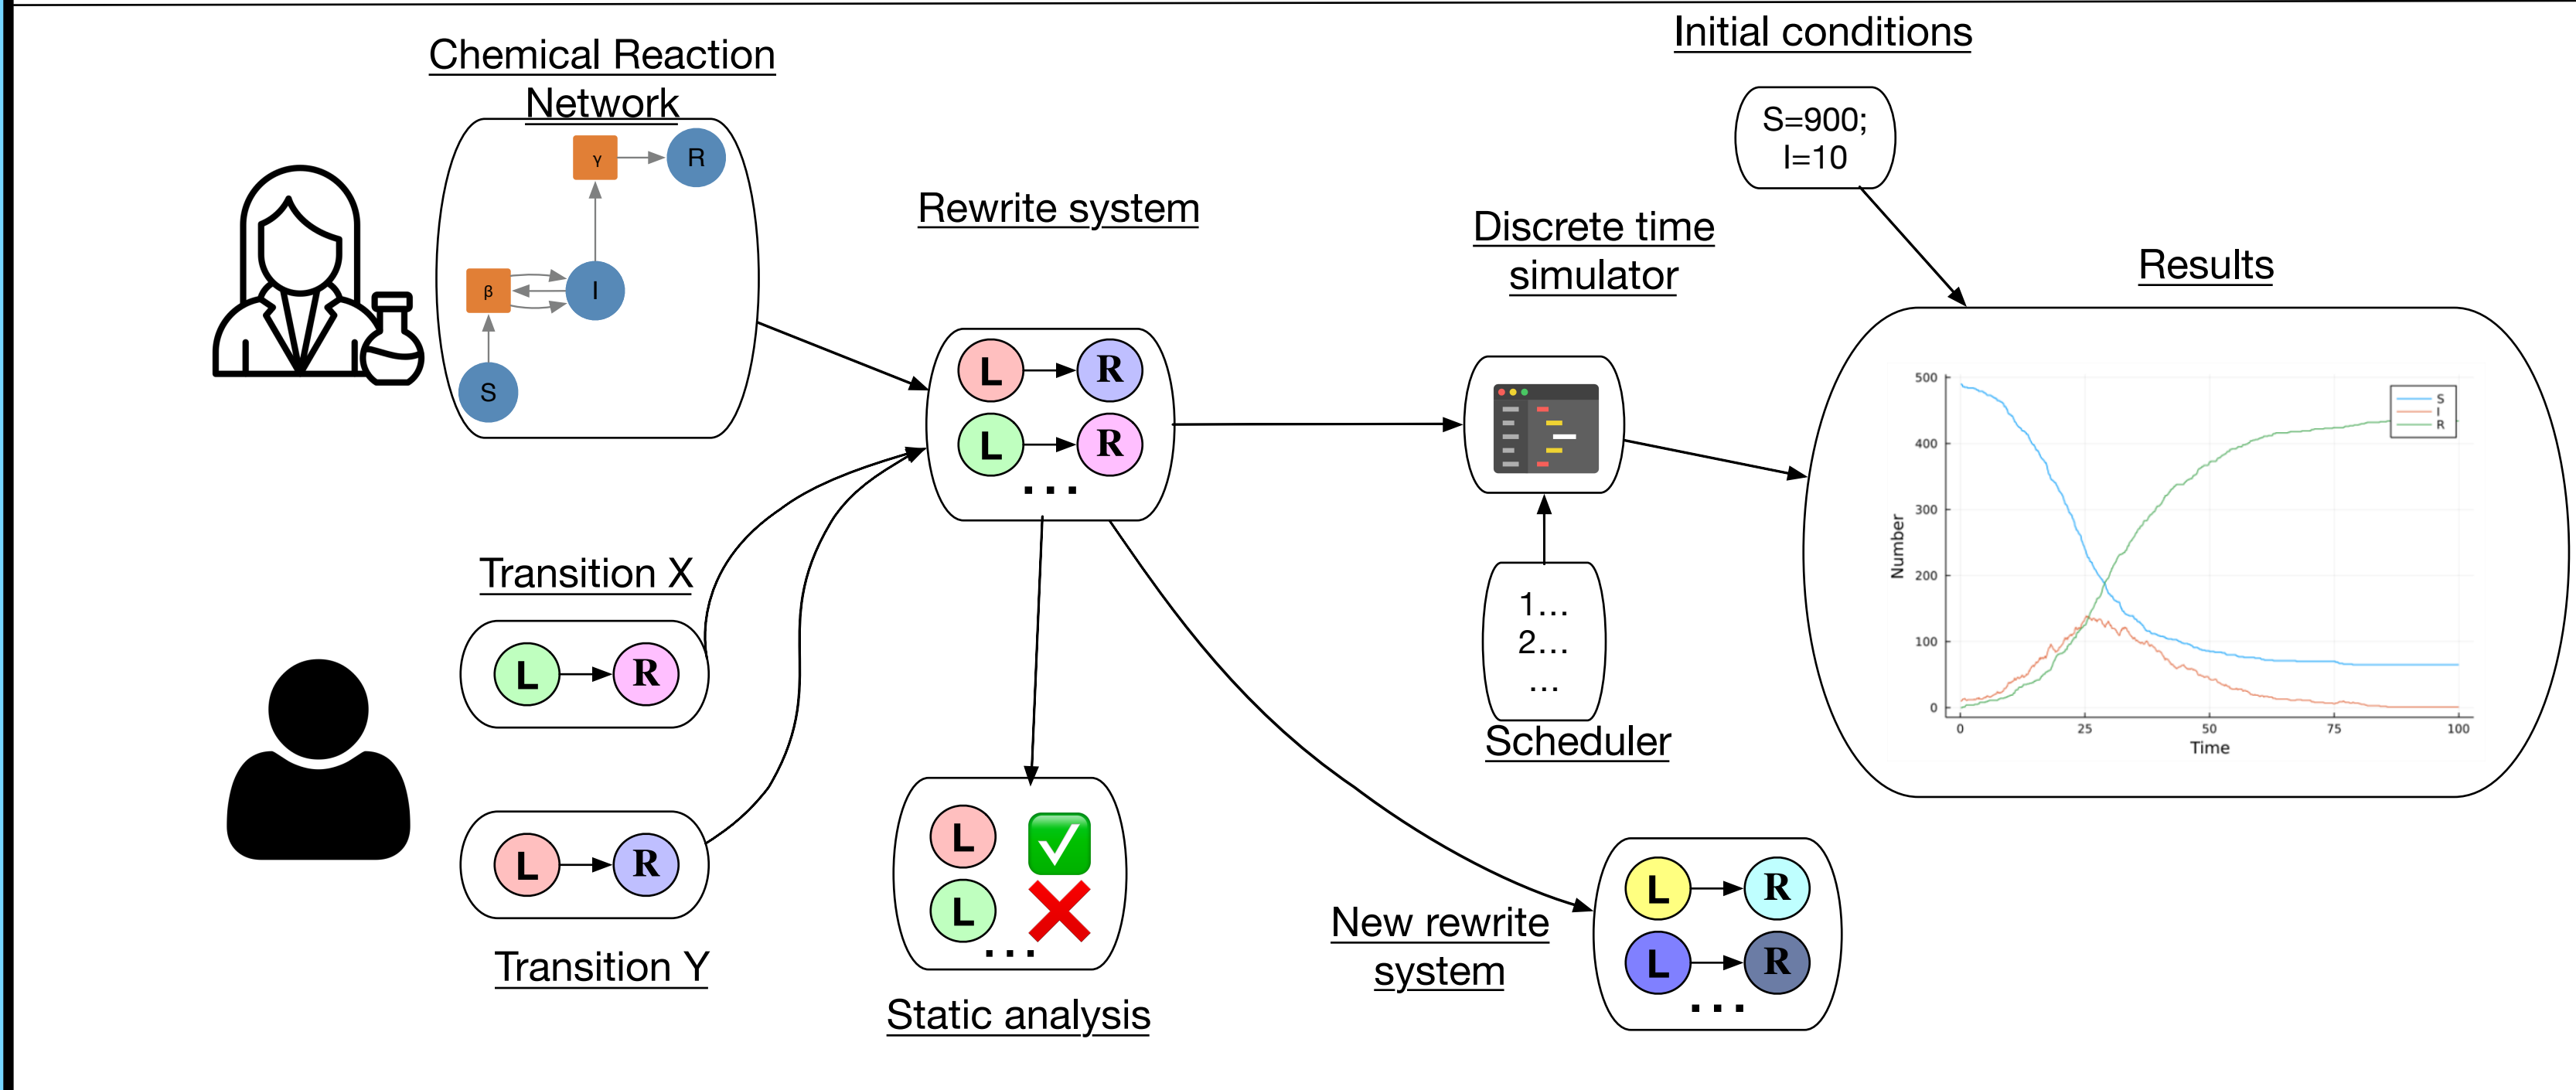

Advection-diffusion multiphysics - compositionally

Multiphysics - evaluated

- ✓ Avoid introducing errors when redoing one's mathematical model, in code
- ✓ Governing equations and boundary conditions can be depicted diagrammatically
- ✓ This allows sophisticated manipulation / construction of multiphysics
- ✓ We can check when one diagram has the same solutions as another, symbolically

Rewriting systems, specified diagrammatically

Solvable tasks: • Perform simulation • Generate terms via a grammar • Equational reasoning

Example rewrite rule (LIR) applied to a state G

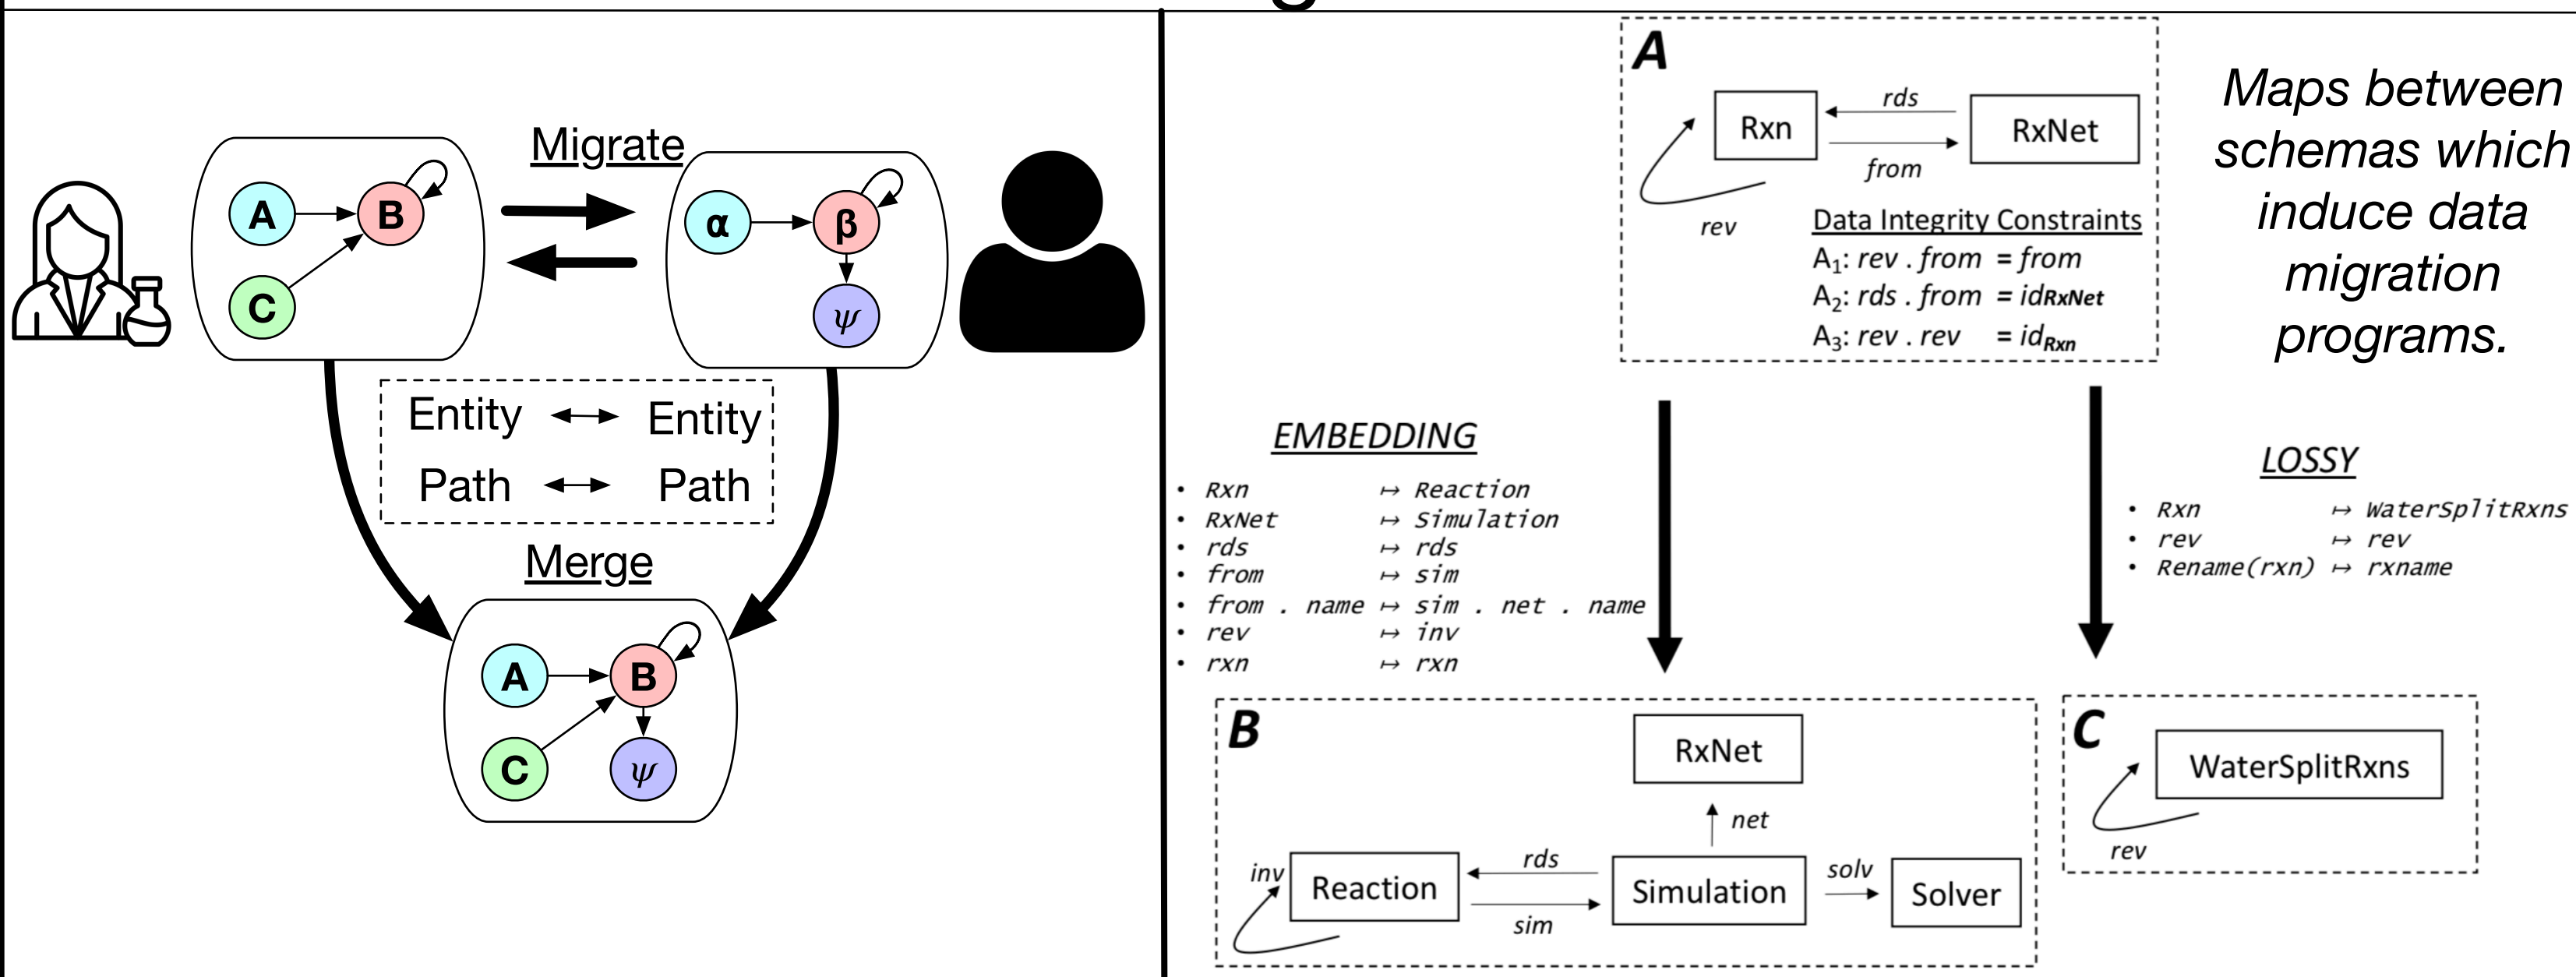

Negative application conditions capture more complex logic, still within a graphical language

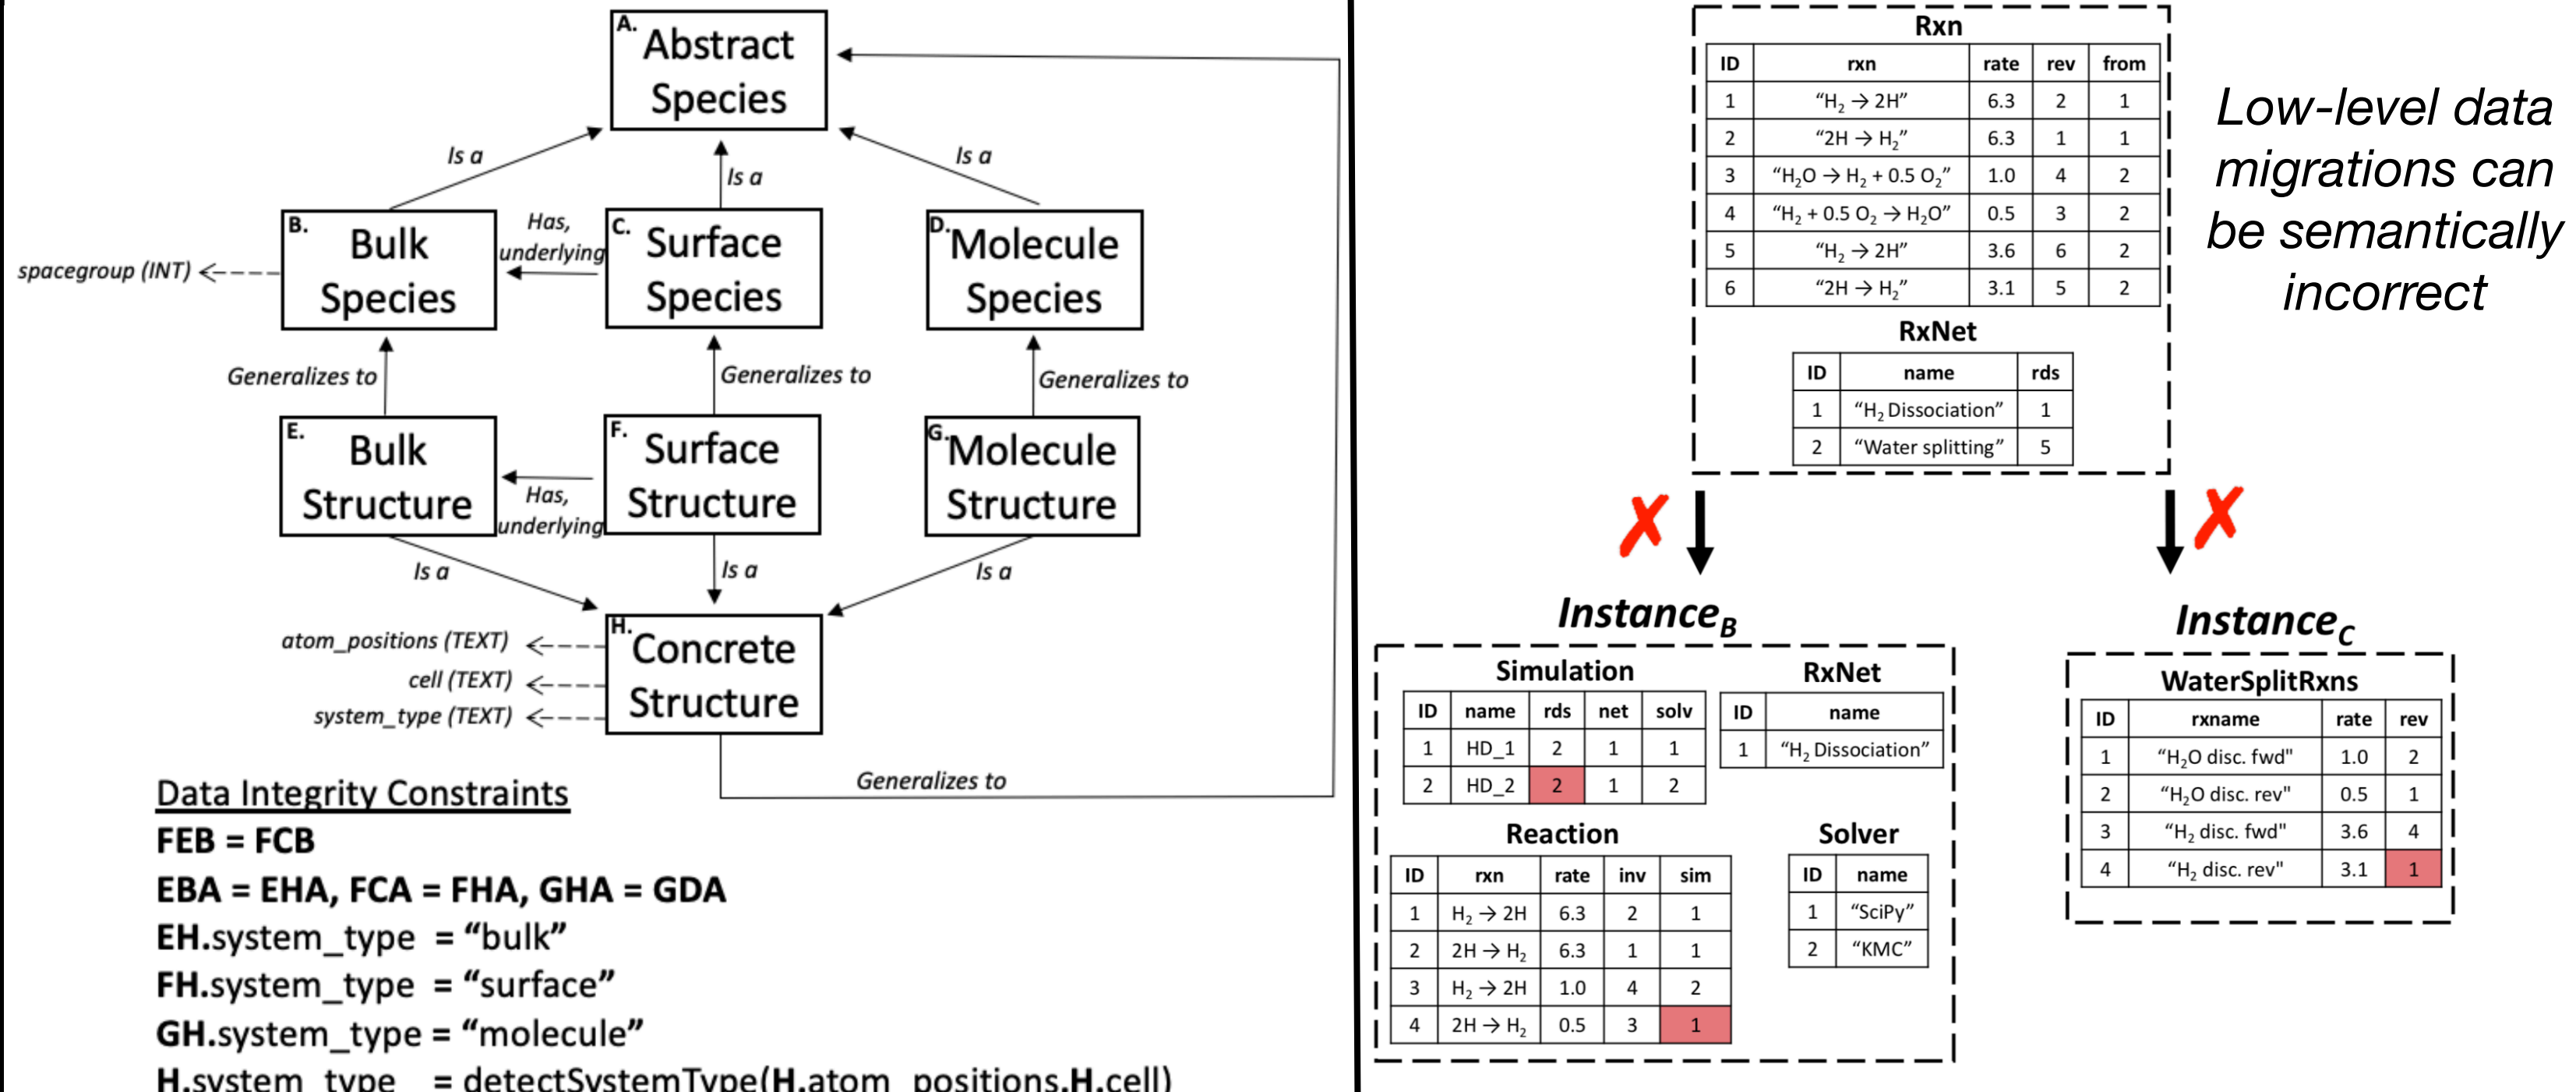

- ✓ Declarative language for a very broad type of program. No code needs to be written!
- ✓ Rewrite systems easier to debug than OOP code - rules are just graphs that can be analyzed independently.
- ✓ CT rewriting naturally gives us provenance and one implementation works over a broad class of data structures (data structure is an input *parameter*).
- ✓ We can perform migrations on our rules when our assumptions change.

Declarative language for meaning-preserving data migrations

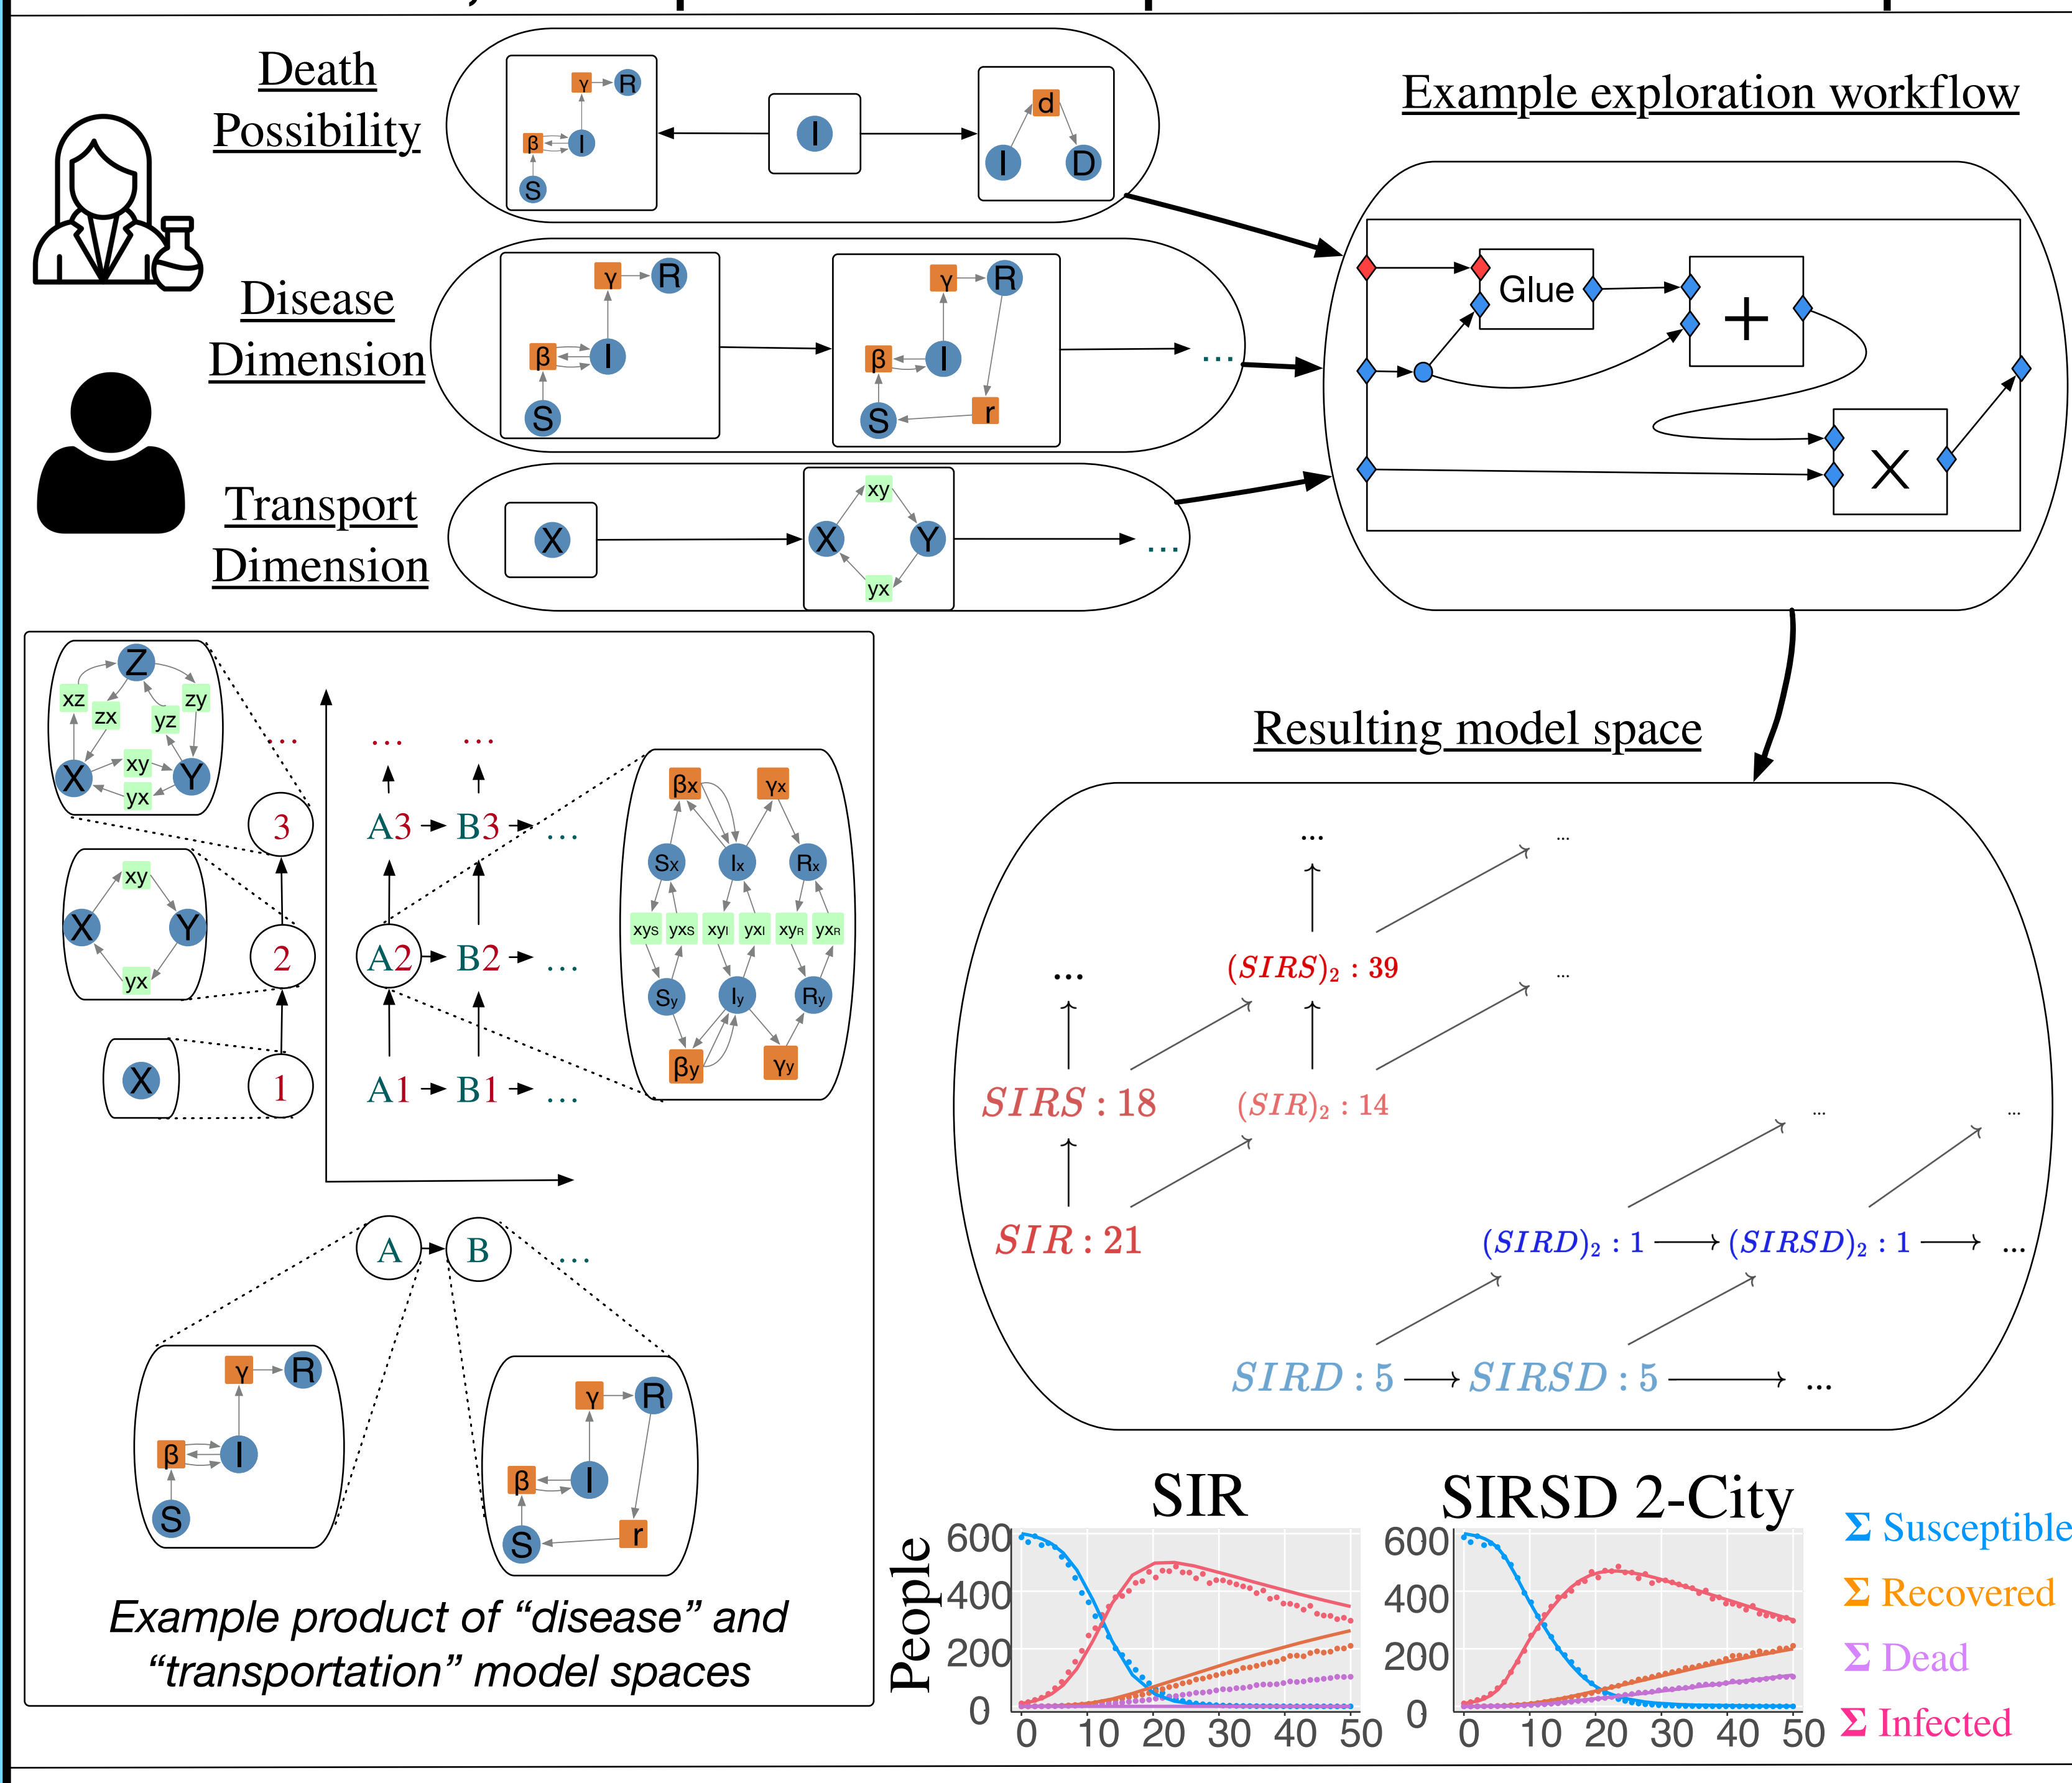

Example schema of chemical structures

- ✓ Mathematically-rigorous data migration induced by high-level schema maps.
- ✓ Data sharers can equip data with constraints; restrict misuse by data receivers.
- ✓ Constraints from data receivers filter data that doesn't meet this specification.

Declarative, compositional exploration of model space

- ✓ Declarative language for specifying and executing the exploration of model spaces
- ✓ Provenance of model components aids analysis and comparison of resulting models
- ✓ Flexible, generic tools for combining smaller model spaces into larger ones
